There have been many results for the system  $\{a^{-m/2}\psi(a^{-m}x - nb)\}_{m,n \in \mathbb{Z}}$  to be a frame for  $L^2(\mathbb{R})$ , where  $a > 1$  and  $b > 0$ . In this talk we first study some general conditions for the system  $\psi_{j,k}(x) = s_j^{-1/2}\psi(s_j^{-1}x - b_k)$ ,  $j, k \in \mathbb{Z}$ , to be a frame, where  $s_j > 0$  and  $b_k$  are reals. First we give a necessary condition which extremely extends the one obtained by Chui and Shi in 1993. Secondly we point out that the necessary condition is also sufficient when  $\psi$  is band-limited, moreover we give sufficient conditions, which exclusively depend on  $\psi$ , for  $\{\psi_{j,k}\}$  to be a frame for a large class of  $\{s_j\}$  and  $\{b_k\}$ . At the last we characterize a bounded measurable  $E$  such that  $\psi$  is a frame function with  $\hat{\psi} = \chi_E$ .

The main results of this paper are as follows.

**Theorem 1** *If  $s_j^{-1/2}\psi(s_j^{-1}x - b_k)$ ,  $j, k \in \mathbb{Z}$ , is a frame with bounds  $A > 0$  and  $B < \infty$ , where  $\psi \in L^2(\mathbb{R})$ ,  $s_j > 0$  and  $\{b_k\}$  is a  $r$ -Fourier frame sequence, then*

$$\frac{A}{B_r} \leq \sum_{j \in \mathbb{Z}} |\hat{\psi}(s_j w)|^2 \leq \frac{B}{A_r}, \text{ a.e.}$$

**Theorem 2** *Suppose  $\psi \in B_\Omega \cap L(\mathbb{R})$  for some  $\Omega > 0$ , where  $B_\Omega = \{f \in L^2(\mathbb{R}) : \hat{f}(w) = 0 \text{ for any } |w| > \Omega\}$ , and  $s_j > 0$ . Then the following two assertions are equivalent: (i) There is a  $r$ -Fourier frame sequence  $\{b_k\}$  with  $r > 2\Omega$  such that  $\psi_{j,k}(x) = s_j^{-1/2}\psi(s_j^{-1}x - b_k)$ ,  $j, k \in \mathbb{Z}$ , is a frame for  $L^2(\mathbb{R})$ ; (ii)  $a \leq \sum_{j \in \mathbb{Z}} |\hat{\psi}(s_j w)|^2 \leq b$ , a.e., for some  $a > 0$  and  $b < \infty$ . Furthermore if (ii) is satisfied, then  $\{\psi_{j,k}\}$  is a frame for any  $r$ -Fourier frame sequence  $\{b_k\}$ , where  $r > 2\Omega$ .*

**Theorem 3** *Suppose  $\psi \in B_\Omega \cap L(\mathbb{R})$  for some  $\Omega > 0$ . If  $|\hat{\psi}(w)| \leq A|w|^\alpha$  near  $w = 0$  for some  $A > 0$  and  $\alpha > 0$  and  $0$  is an isolated zero of  $\hat{\psi}(w)$ , then  $\{s_j^{-1/2}\psi(s_j^{-1}x - b_k)\}_{j,k \in \mathbb{Z}}$  is a frame for  $L^2(\mathbb{R})$  for any sequence  $\{s_j\}_{j \in \mathbb{Z}}$  of positives satisfying  $0 < \inf_j \frac{s_j}{s_{j+1}} \leq \sup_j \frac{s_j}{s_{j+1}} < 1$  and any  $r$ -Fourier frame sequence  $\{b_k\}_{k \in \mathbb{Z}}$ , where  $r > 2\Omega$ .*

**Theorem 4** *Suppose that  $E$  is a bounded set with  $0 < m(E) < \infty$ ,  $a > 1$  and  $\hat{\psi}(w) = \chi_E(w)$ . Then  $\psi$  is a frame function for this  $a$  and some  $b > 0$ , if and only if there is an integer  $K$  such that*

$$E_+ \triangleq E \cap (0, \infty) = \bigcup_{k=-\infty}^K a^k A_k, \quad E_- \triangleq E \cap (-\infty, 0) = \bigcup_{k=-\infty}^K a^k B_k,$$

where  $\{A_k\}_{k \leq K}$  and  $\{B_k\}_{k \leq K}$  are finitely disjoint partitions of  $(1, a]$  and  $[-a, -1)$  respectively. Furthermore when the condition (??) is satisfied,  $\psi$  is a frame function for this  $a$  and any  $b$  with  $0 < b < \frac{1}{\sup E - \inf E}$ .
